Create Project Response #3

1a. **TITLE:** Tristen Erpelding, CSCI 101 Section H, HTML Modular Web Scrapper

1b. **PROGRAM:** The program I am going to write is an HTML web scrapper that will parse the HTML code on a webpage. The user will input a webpage they want to parse. Then the program will print out all the different tags that the user can select from that they want to copy. After the user selects the tags they want, the program will copy the text within the tags and save that data in a file.

3a. **EXECUTION:** It is important to know that my program uses two import modules that are not included in the default python install. Those modules are requests and beautifulsoup4, to install these modules please refer to the README.txt in the provided zip file.

How To Use:

1. Enter the URL you would like to scrape html data from
2. Type the corresponding number associated with the tag you would like to get data
3. Repeat step 3 until you have selected all the tags you want
4. Input nothing to move to next step
5. Enter the filename name you wish to store all the data to (include ".csv" at the end)
6. Browse to csv file to see all the data

Example:

1. Enter URL> https://www.geeksforgeeks.org/
2. CHOICE> 13
3. CHOICE> 14
4. CHOICE> 19
5. CHOICE>
6. Enter Filename> scrapedData.csv

3b. **REFLECTIONS:** In this project I learned to how to do GET web request in python and be able to extract the html of the webpage. Along that I was able to process all the tags within the code and display its content to the user. If I were to redo the program, I would change how I display the tags to the user and how the user inputs which tag they want. I would also add in a check for when the user types in a filename to see if it has the .csv extension. If so, then leave it if not then add it and if has any other extension attached then prompt the user with an error.

Word Count: 161
